Southern Sumatra Earthquake in 2007

September 12, 2007

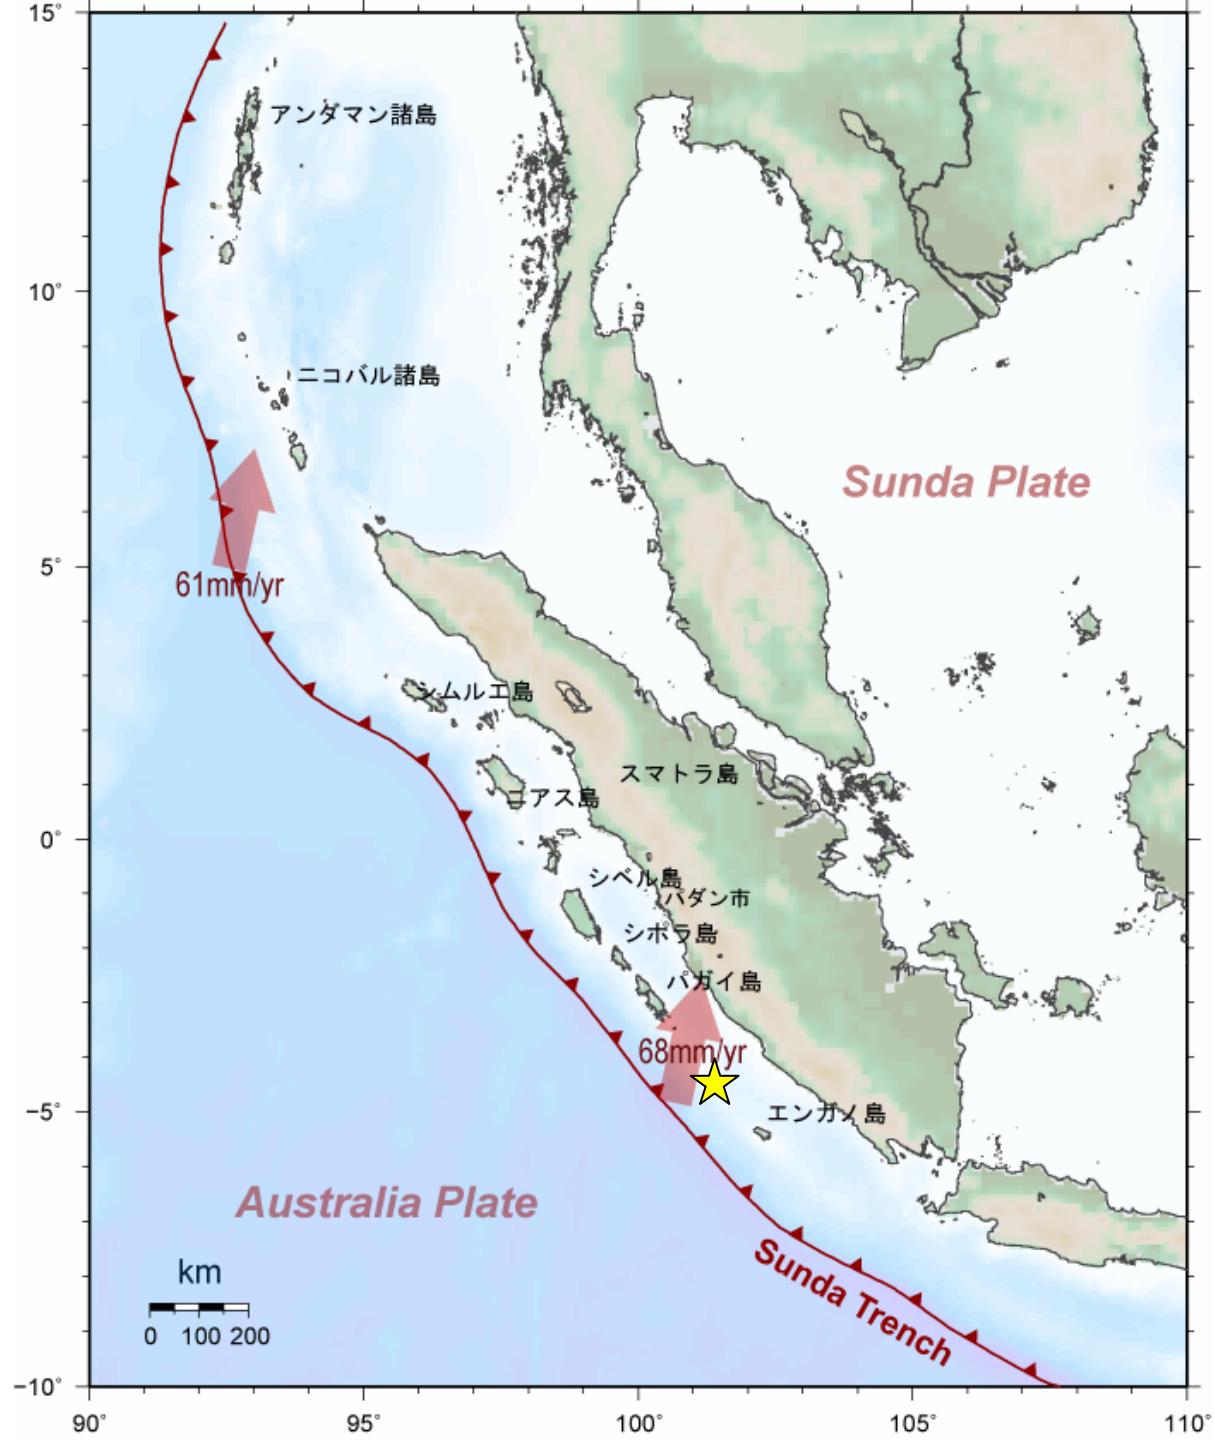

18:10 (Local time)

Depth: 30 km

Mw 8.4 (USGS)

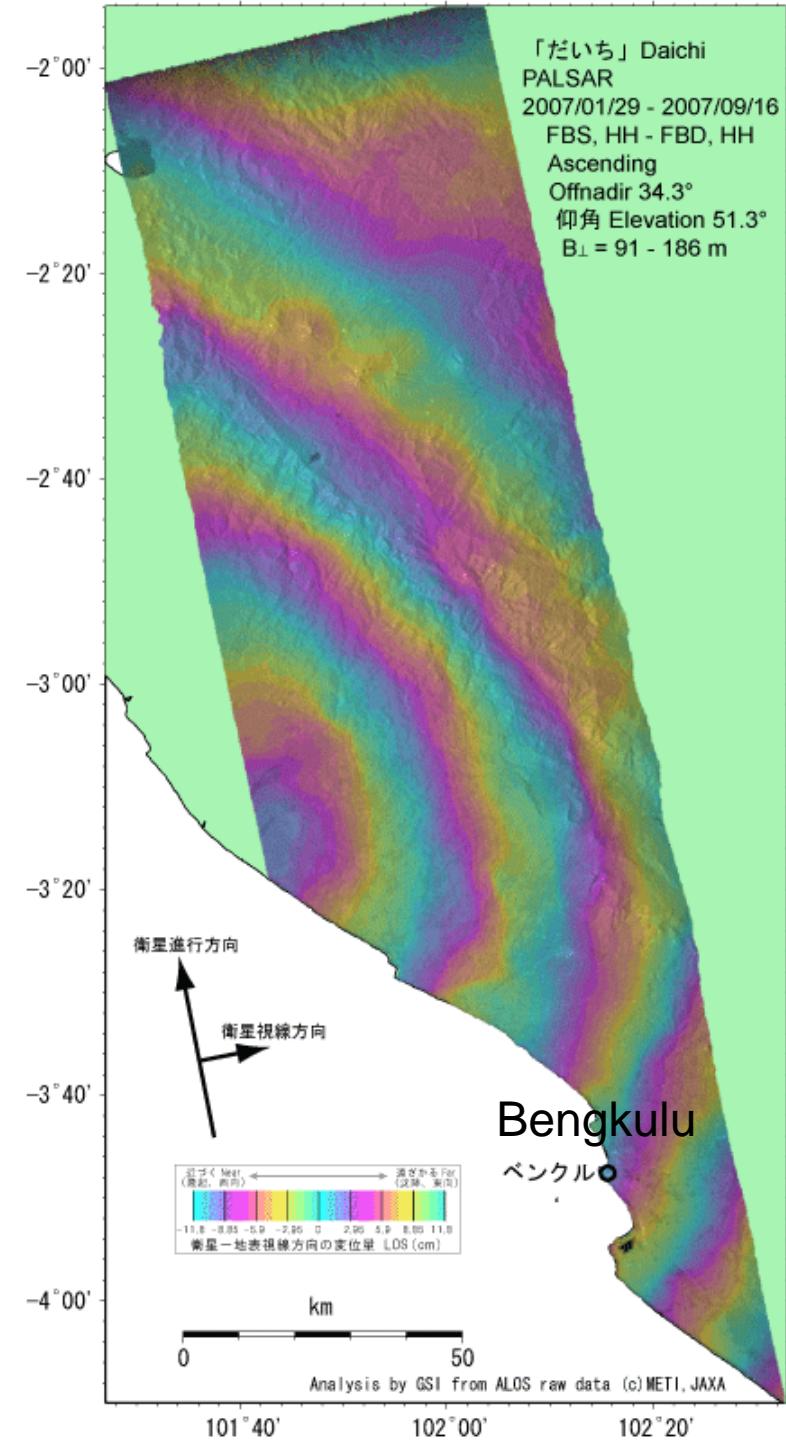

死者数 25名

Sunda plateとAustralia plateのプレート境界で発生した逆断層型の地震

Daichi Interferogram of 2007 S. Sumatra Earthquake around Bengkulu, Indonesia

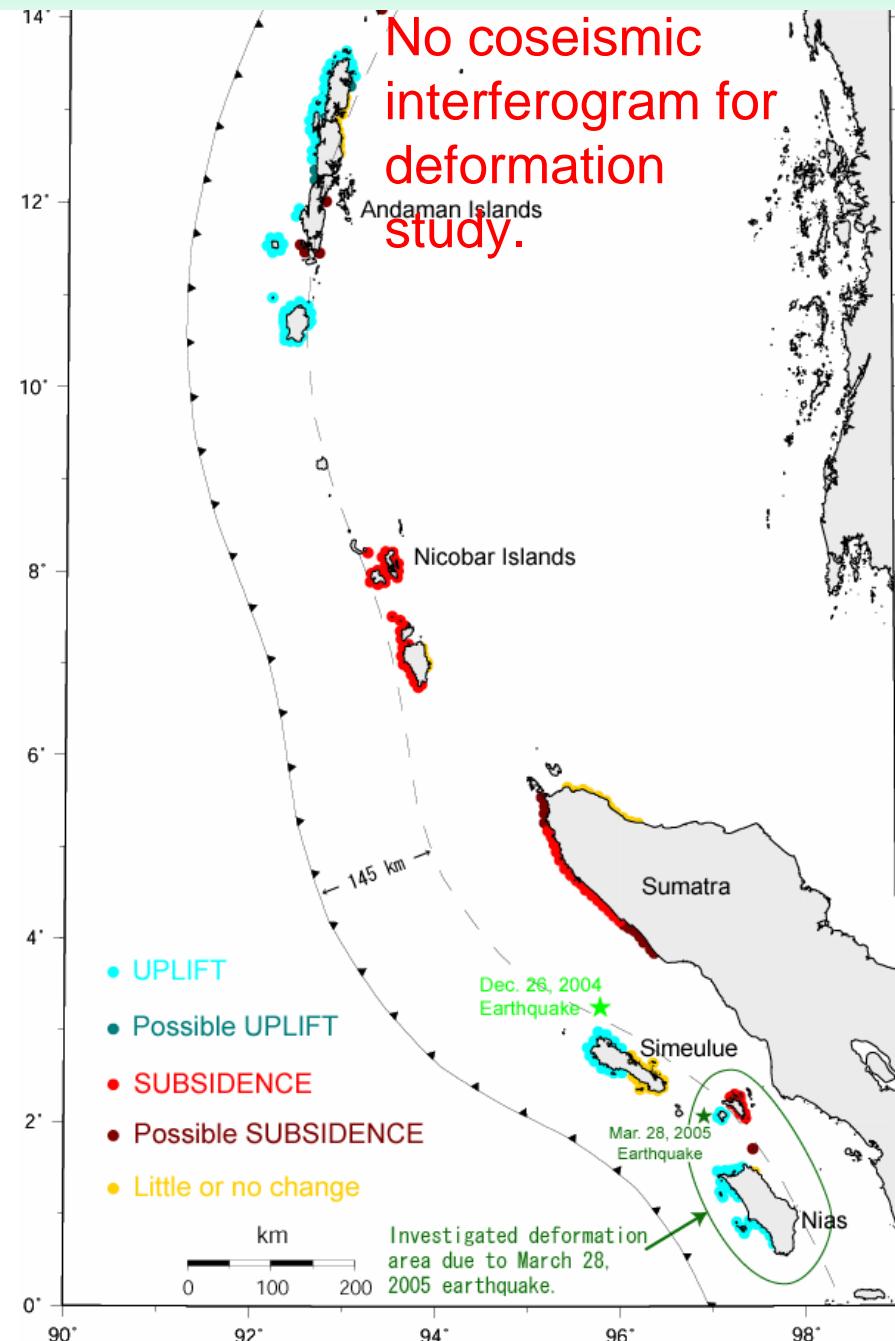

Jan 29 – Sep. 16, 2007 (Coseismic)
4 scenes were concatenated.
Completely correlated!

Past Study: Presented at Padang, Indonesia in August, 2005.

CONCLUSION

- (1) We processed about 60 scenes of SAR data and made a map showing vertical displacements of the ruptured area caused by the 2004&2005 Sumatra earthquakes.
- (2) Two earthquakes ruptured about 1,670 km long area.
- (3) A line approximately 145 km east from the trench separates west uplifted zone from east subsided zone.
“Just a coincidence?”
“Nature is more complicated.”
“But this is also the fact...”

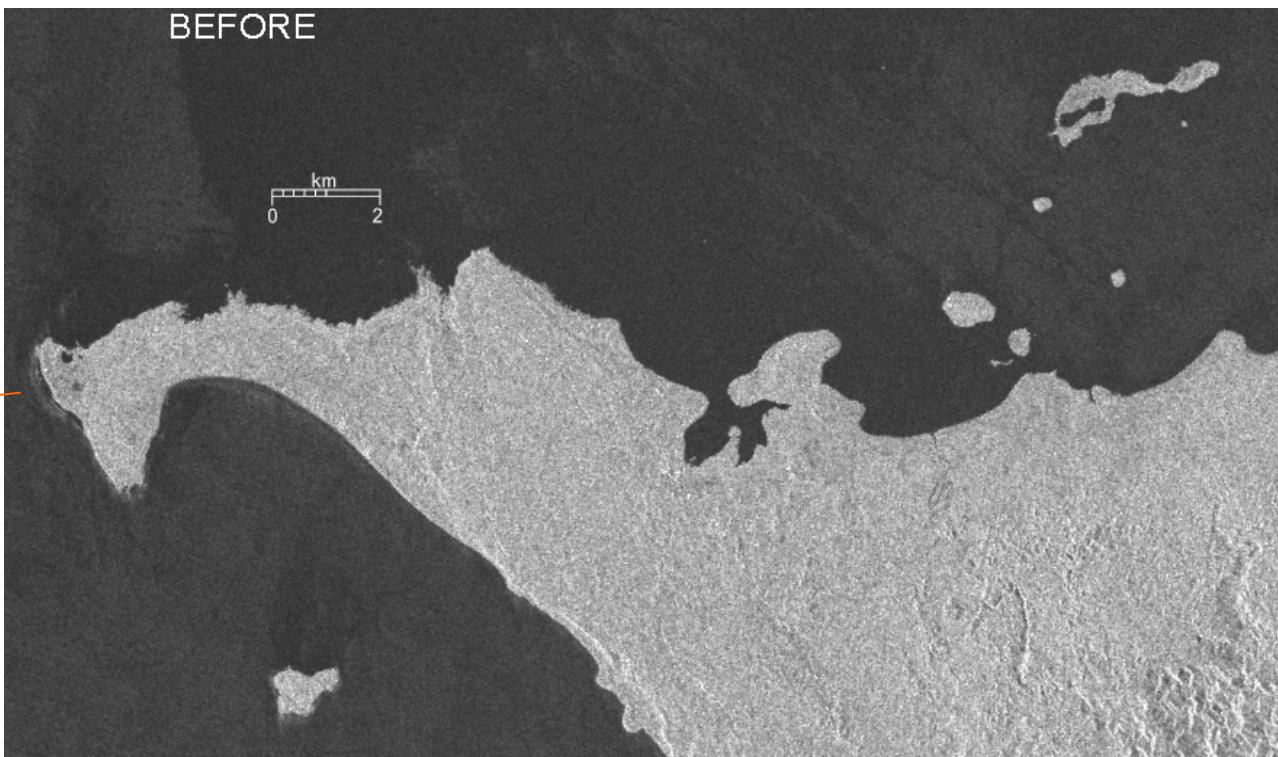

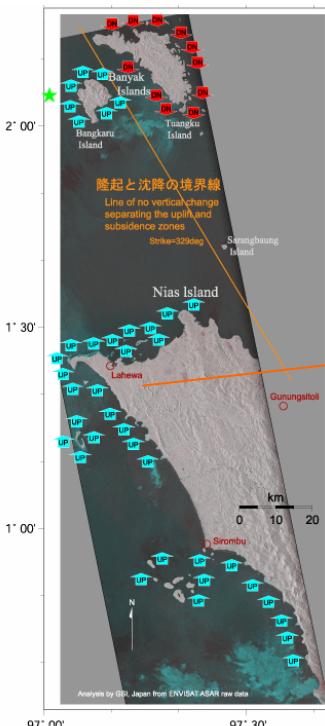

Past Study: Presented at Padang, Indonesia in August, 2005.

Coastal changes in Nias I. caused by the 2005 Sumatra earthquake extracted from SAR images

More than 10 new islands were created, which length is 100 m to 1.5 km.

emergence due to uplift

ENVISAT ASAR images of Nias island, Indonesia

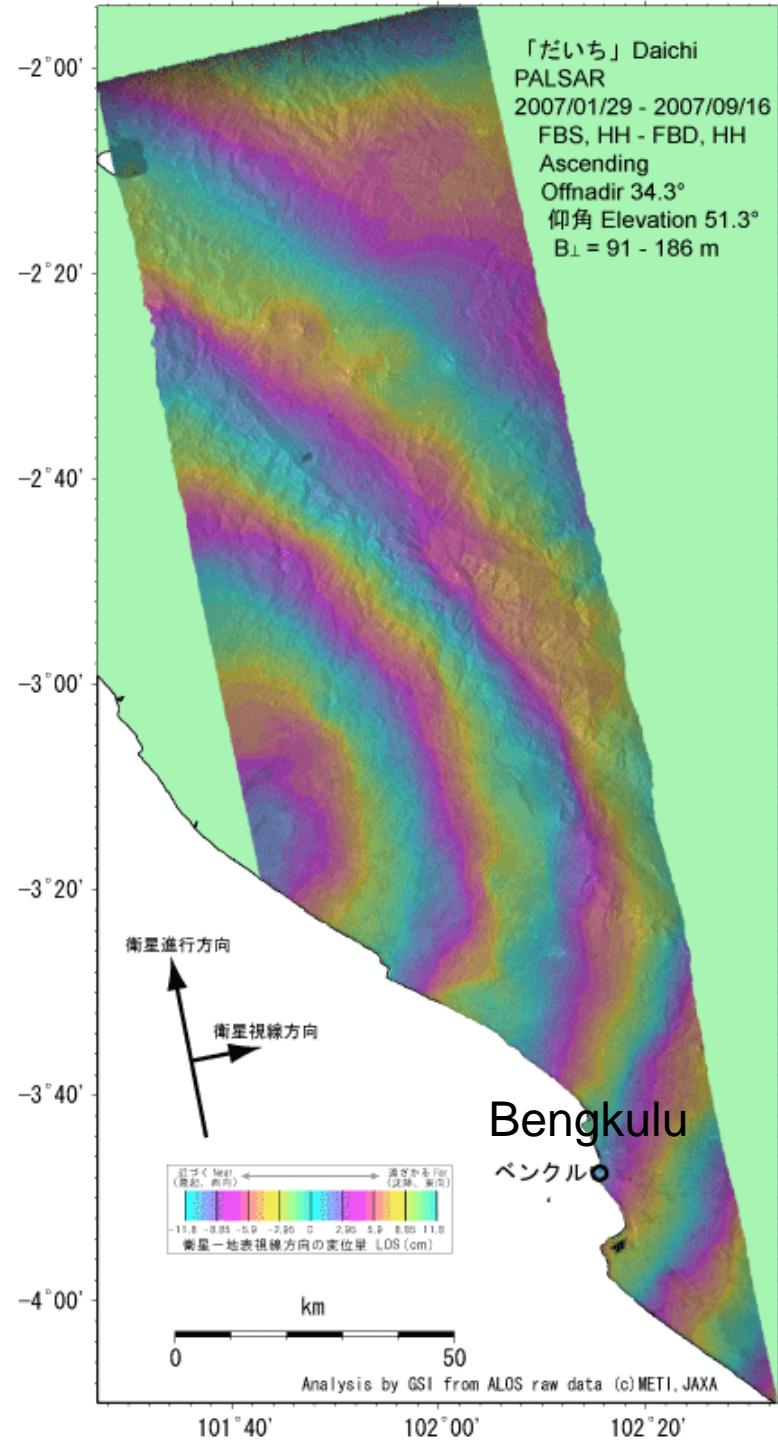

Daichi Interferogram of 2007 S. Sumatra Earthquake around Bengkulu, Indonesia

Jan 29 – Sep. 16, 2007 (Coseismic)

4 scenes were concatenated.

Completely correlated!

わかる。

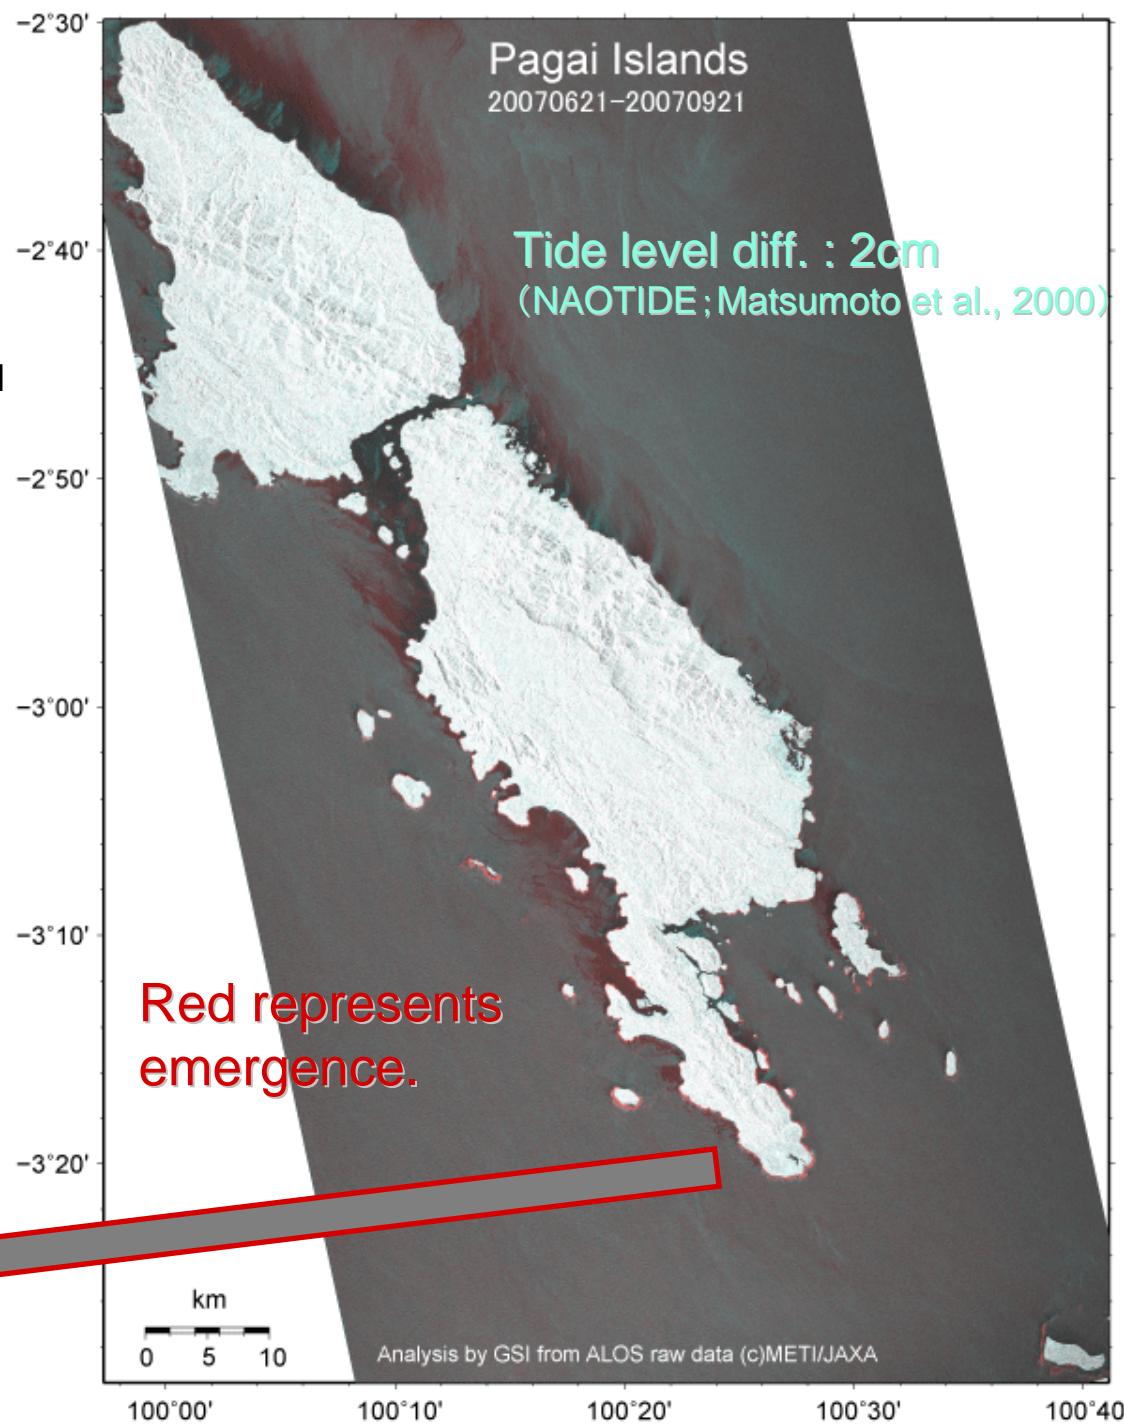

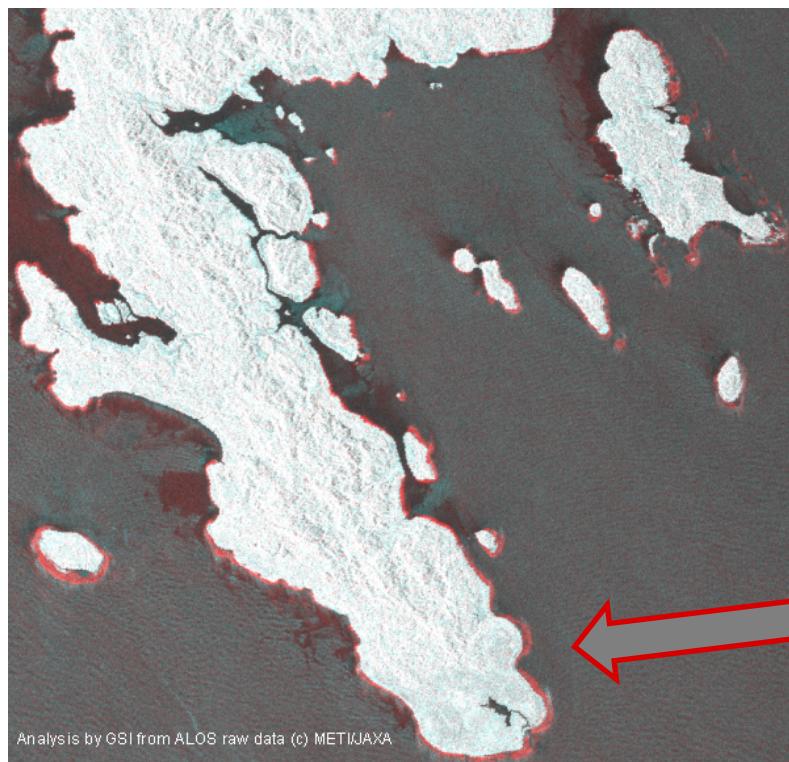

Coseismic uplift of S. Pagai Is. extracted from comparison of SAR intensity

2007 earthquake pushes up cluster of 6 new islands.

The emergence had increased the size of small islets and even produced more than six new small islets. The length of the maximum islet is approximately 1.6 km.

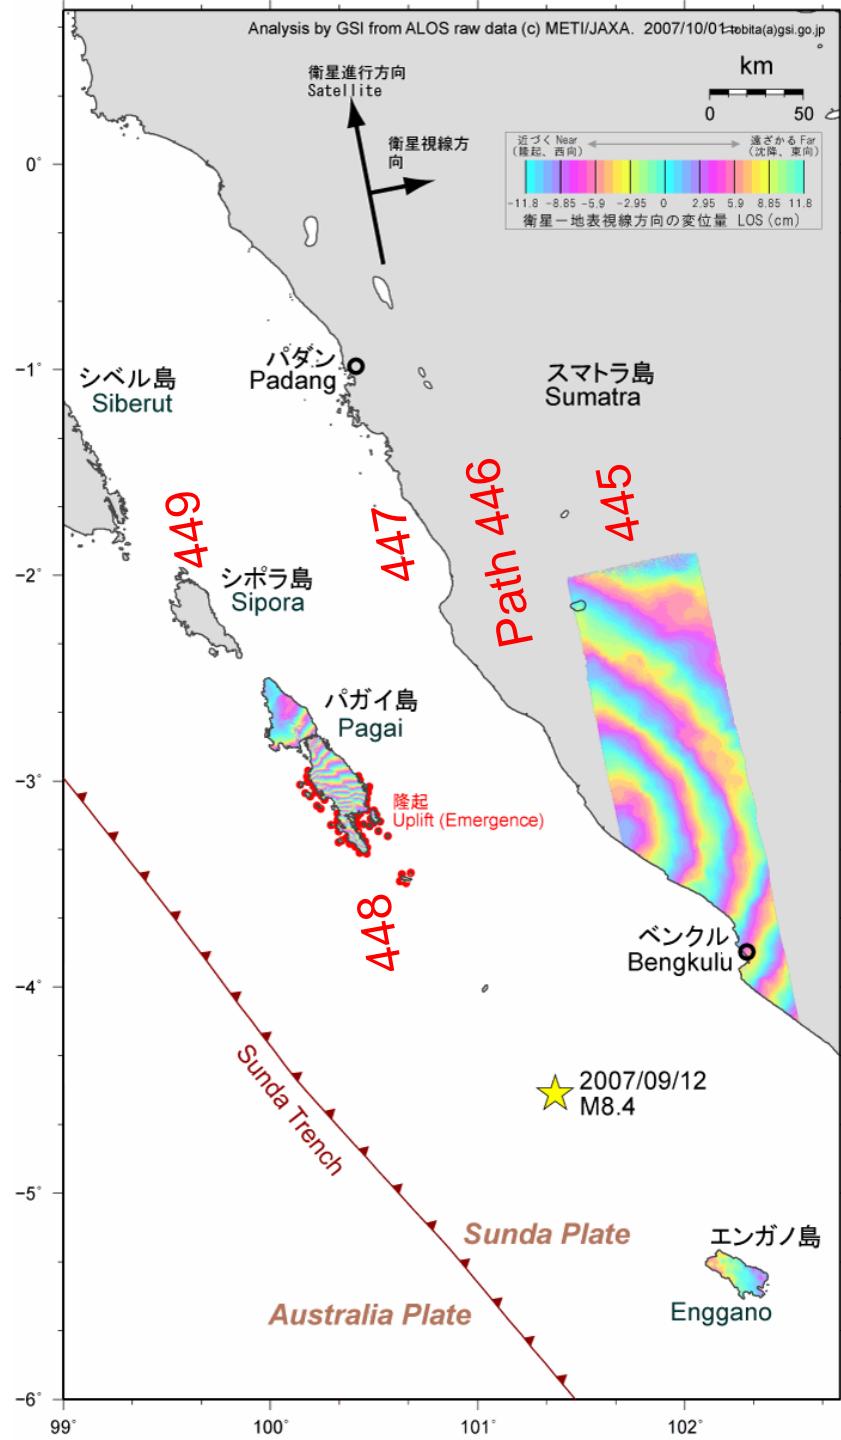

Up to 500 m wide emergence of reef is seen in the bottom left island in this image.

SAR interferograms and distribution of uplifted coastline

We generated preseismic, coseismic and postseismic interferograms of ruptured area, paths 445, 446, 447, 448 and 449.

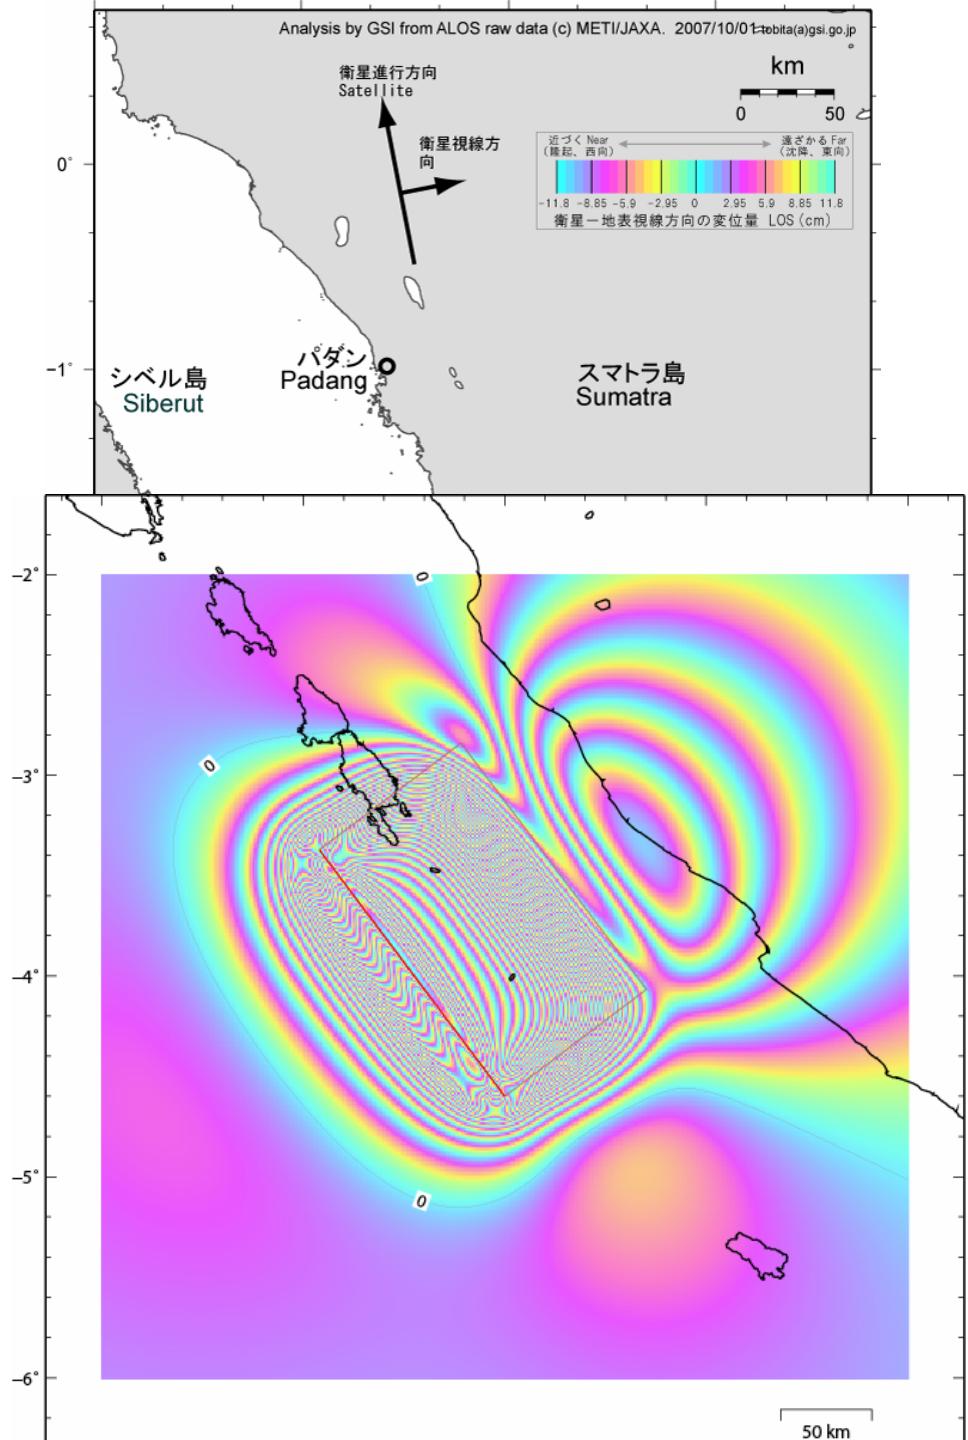

Interferograms with small atmospheric phase were selected for this study.

First approximation of SAR interferograms by a rectangular fault model

A rectangular fault model with uniform slip can explain roughly the phase gradients.

But this simple model cannot explain the phase in Pagai and Enggano islands in detail.

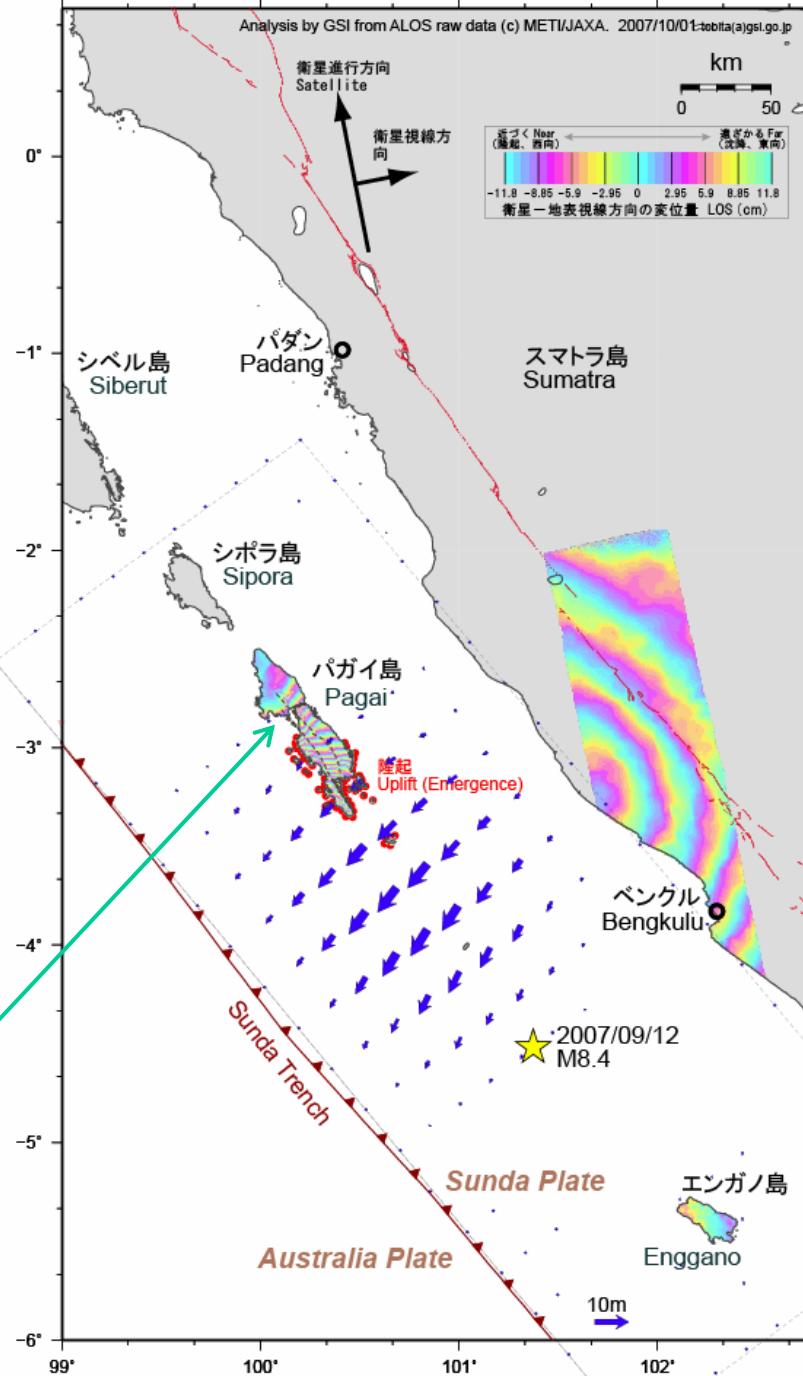

SAR interferograms and estimated slip distribution on the plate boundary

We estimated the **slip distribution** of the 2007 S. Sumatra Mw8.4 earthquake from displacements observed by Daichi (ALOS) .

Assumed Dip: 12°

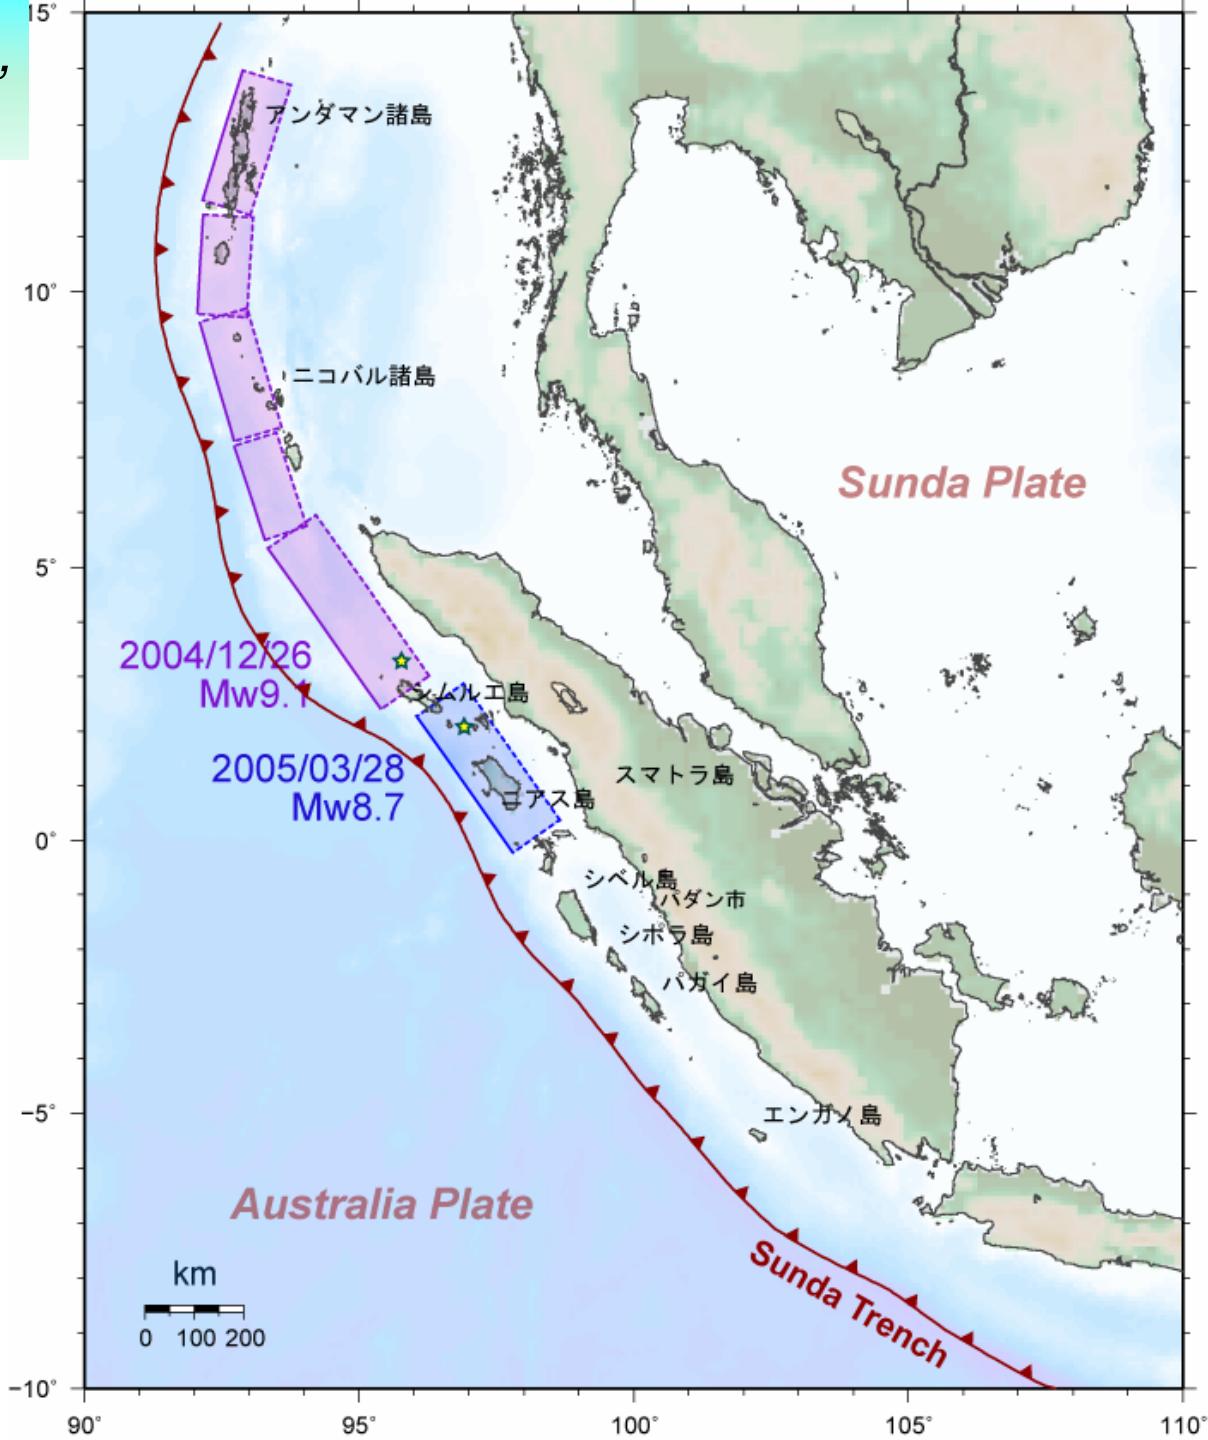

2007 event rupture is **260 km** long along Sunda Trench.

North end of rupture is **between S.** and N. Pagai Islands.

結論 Conclusion of analysis of 2004 and 2005 earthquakes

海岸線の隆起沈降という上下地殻変動から推定される断層モデルによれば、2004年12月26日と2005年3月28日の地震の破壊域は、重なっておらず、約50kmの間隔で、隣接している。 Barrier?

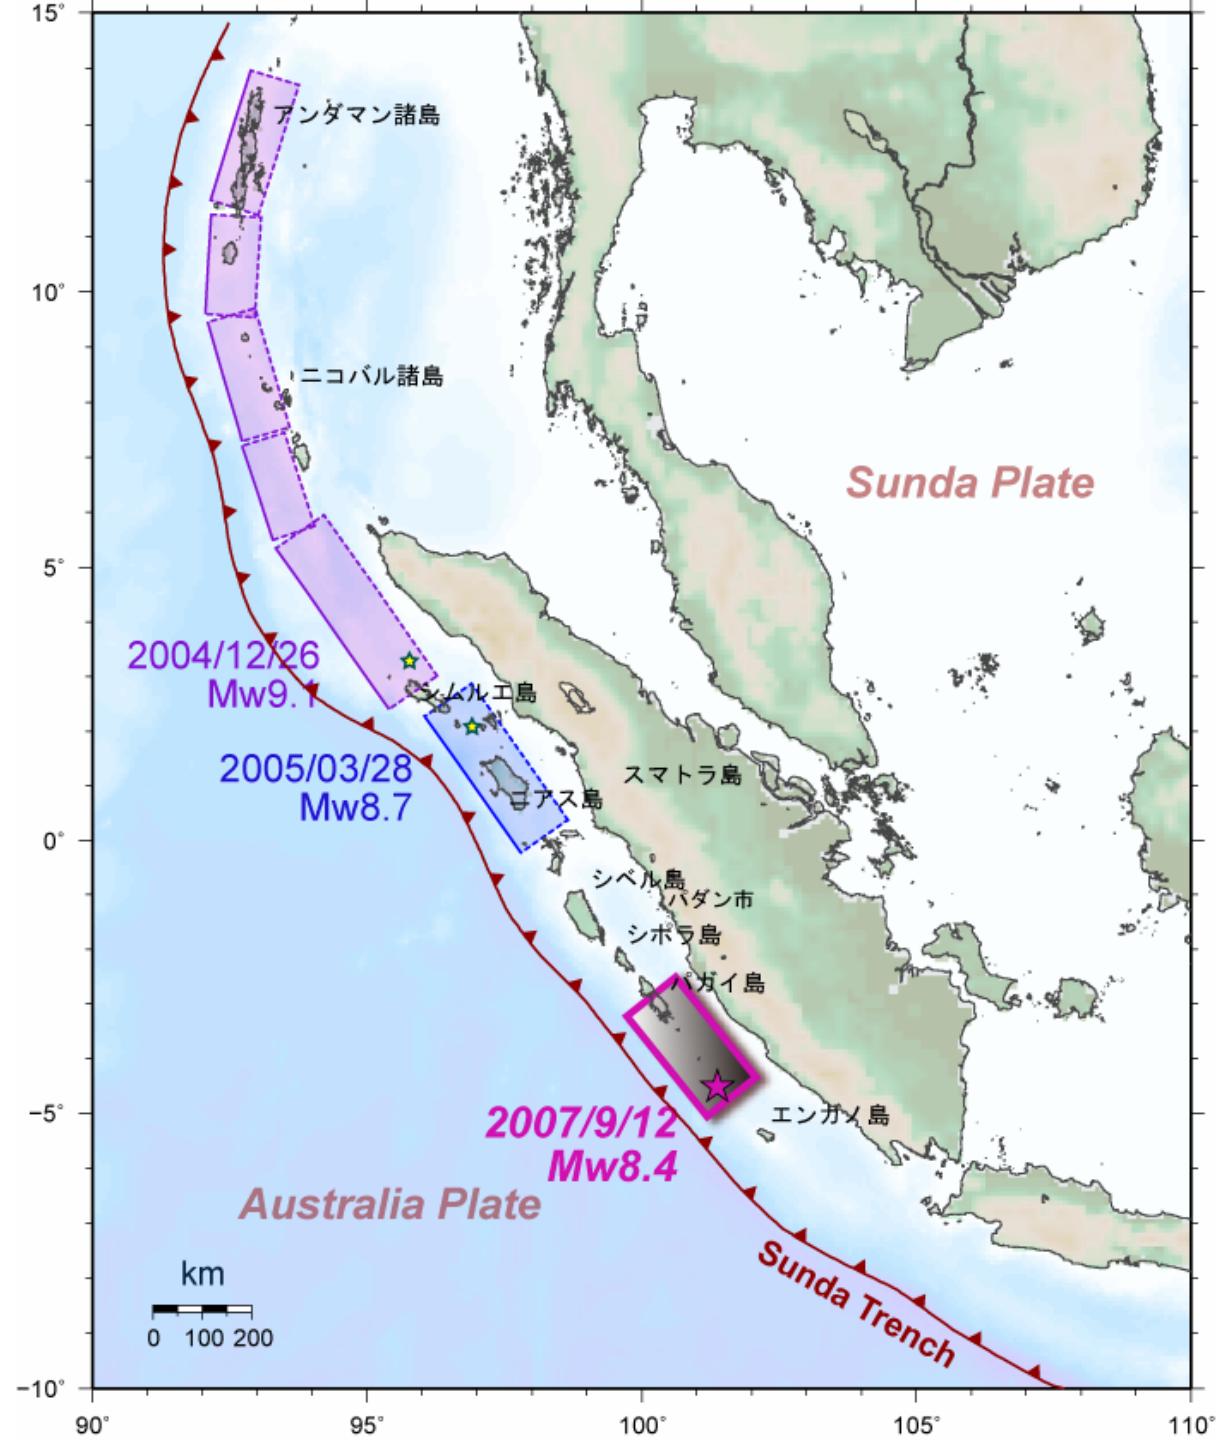

There is a gap between 2004 and 2005 ruptures.

The length of the gap is about 50 km.

Source fault of the 2007 earthquake determined by Daichi SAR image analyses

North end of
rupture is between
S. and N. Pagai
Islands.

The length of the
2007 rupture is
about 260 km.

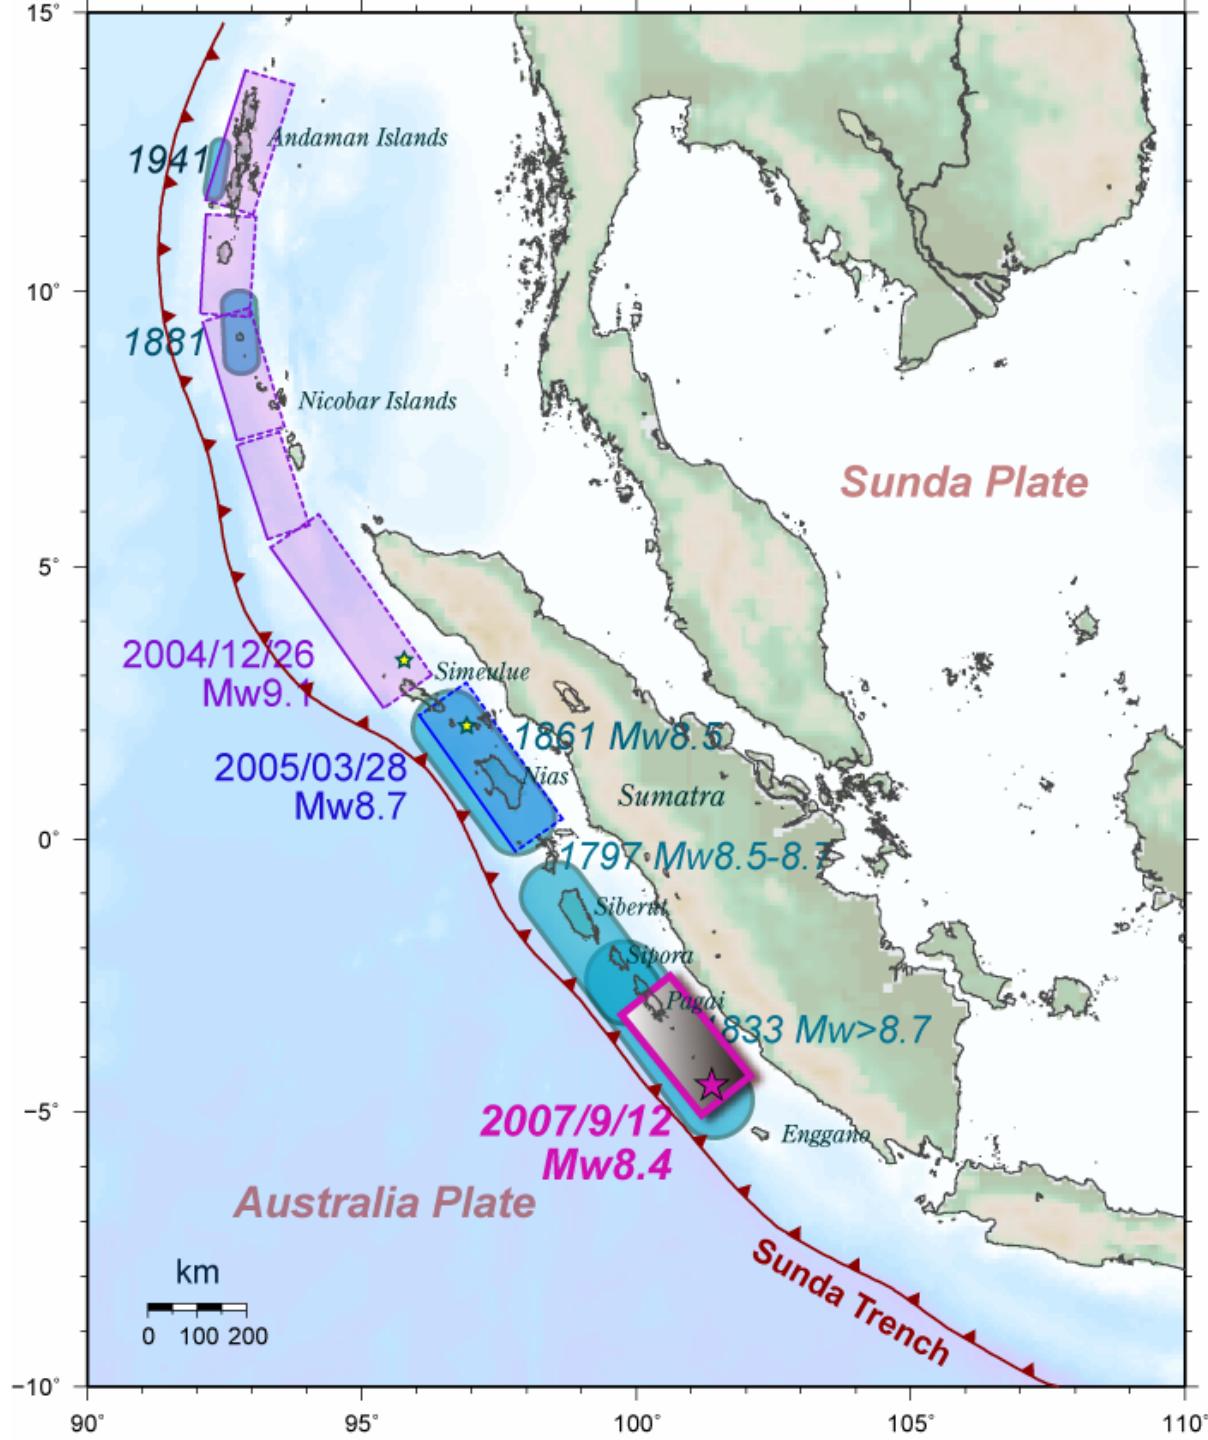

Source faults of recent events and historic earthquakes

予想されるEventによる地殻変動は、Siberut島、Sipora島のPALSAR干渉画像で詳細に観測される可能性が高い。地震前の予兆の有無も確認する必要がある。

Padangや沖の島々(Sikuai島等)では若干の沈降が予想され、津波の被害が増幅されるセンスである。

Conclusion まとめ

- Estimated the **slip distribution** of the 2007 S. Sumatra Mw8.4 earthquake from Daichi (ALOS) interferograms.
- The length of a seismic gap off Padang between the 2007 and the 2005 ruptures is approximately **370 km**.
- Two **discontinuities of phase** were found in **Pagai Islands** (Pulau Pagai), which probably show that the **portion between two normal faults subsided relatively** when the South Pagai Island uplifted coseismically.
